This National Science Foundation (NSF) funded research project is creating and evaluating graphical multi-user virtual environments (MUVES) that use digitized museum resources to enhance middle school students' motivation and learning about science and its impacts on society. MUVES enable multiple simultaneous participants to access virtual contexts, to interact with digital artifacts, to represent themselves through “avatars,” to communicate with other participants and with computer-based agents, and to enact collaborative learning activities of various types. Initially, MUVES were based only on textual descriptions); now, many MUVES are graphical in nature, or use graphics to enhance textual descriptions. Our project's educational environments are extending current MUVE capabilities in order to study the science learning potential of immersive simulations, interactive virtual museum exhibits, and "participatory" historical situations (<http://www.virtual.gmu.edu/muvees/>). To accomplish this, we have built our own MUVE shell based on the Sense8 WorldToolKit (<http://www.sense8.com/>).

Our MUVES are not stand-alone learning environments, but instead are designed for use in a classroom context, supplemented by conventional instructional activities such as textbooks and teacher-led discussions. Hard-copy outputs, including both lab-notebook answers and written letters to the “mayor” provide methods for teacher assessment; teachers use them to determine when to “promote” a student to the “next level” in a unit. Our virtual learning environments function on bandwidth as low as a 56K modem and on Windows desktop computers with at least 450 Megahertz processing speed and 64 Megabytes of RAM, well within the specifications of machines currently being purchased by schools.

Our project is studying how the design characteristics and usability of MUVE learning experiences affect middle school students' motivation and educational outcomes. We are focusing on the extent to which guided inquiry and mentoring using digitized museum artifacts in virtual contexts can aid pupils' performance both on classroom assessments and on high-stakes tests related to national science standards. In this research, we are studying pedagogical strategies that foster strong learning outcomes across a wide range of individual student characteristics (e.g., prior experience with computers, knowledge about and interest in science, gender, ethnicity, linguistic proficiency in English). Interaction in the MUVES involves substantial reading and writing, so we are providing all student materials in both English and Spanish to study the effects of this intensive textual interaction in enhancing multi-lingual communication and literacy.

In particular, we are working to dramatically improve the educational outcomes of the bottom-third of students, pupils who even by middle school often have given up on themselves as learners. These students are disengaged from schooling and typically are difficult to motivate even by good teachers using inquiry-based pedagogy. We are studying whether educational

MUVEs with deep content and challenging activities that resemble the entertainment and communication media these students use outside of school can reengage them in learning. Our research is also examining the implementation process needed to successfully integrate MUVEs in typical classroom settings. Our long-range goal is to develop "replacement" units that—through simultaneously developing students' knowledge in science, mathematics, history, and social studies—enable the teaching staff to utilize inquiry methods capable of covering the same span of content in a similar amount of time required by presentational teaching of this material one topic at a time. Given current educational "reforms" based on an overcrowded curriculum driven by high-stakes, low-level tests, this is essential for any scalable curricular intervention.

Partners in this research are Harvard's Graduate School of Education, the Virtual Environments Lab at George Mason University, the Smithsonian's National Museum of American History (NMAH), and Thoughtful Technologies, Inc. The development team includes education researchers, science educators, instructional designers, computer scientists, museum archivists and exhibit designers, graphic artists, scientists, and middle-school science teachers from both public and private schools. We are documenting our design process to develop heuristics generalizable to other groups developing educational multi-user virtual environments. This study reports on a "River City" curriculum unit on which we have conducted pilot implementations in public school classrooms in Arlington, VA and Boston, MA.

## **DESIGN AND DEVELOPMENT**

Our initial design started with the problem areas identified by science teachers. They were interested in experimenting with something that addressed difficult parts of the curriculum, not the relatively easy parts for which there were already several acceptable instructional strategies available to them. For middle school, the teachers identified experimental design as most difficult concept for students to learn and the one for which teachers were most eager to find an alternative instructional method. In particular, it was thought that an activity in which students had to behave as scientists while they identified a problem through observation and inference and then formed and tested hypotheses would be most valuable. We also wanted something that would be easy for teachers to use in the classroom, so we incorporated hard-copy "lab notebooks" which students use throughout the unit to guide their inquiry while providing a familiar way for teachers to assess student progress through the unit and learning of the science content.

We have developed two prototype middle school science curriculum units, each based around the national science standards, content typically covered in the middle school science curriculum, and the types of investigative process skills necessary for students to do an independent science fair project. Each unit consists of a multi-user virtual environment with virtual contexts and digital artifacts that directly and implicitly guide learner investigations. Student materials for one of the units are in both English and Spanish. Our first curriculum prototype (the River City Unit) centers on content in biology and ecology and is the topic of this paper. The second curriculum prototype (the Bicycle unit) focuses on the physical and material sciences and is centered around problems of bicycle design related to Newtonian motion.

The River City unit is based on students collaboratively investigating a virtual "world" consisting of a city with a river running through it, different forms of terrain that influence water runoff, houses, industries, and institutions such as a hospital and a university. The learners

themselves populate the city, along with non-player characters (NPCs), digital objects that can include audio or video clips, and computer-based agents. River City contains over fifty digital objects from the Smithsonian's collection, plus "data collection stations" that provide detailed information about water samples at various spots in the world. Figure 1 is a screen shot depicting a "birdseye" view of this city. (All figures are at the end of the paper.)

River City is typical of the United States in the late nineteenth century; Figure 2 depicts how we use museum artifacts to illustrate building exteriors and street scenes from that period in history. Content in the right-hand interface-window changes based on what the participant encounters or activates in the virtual environment. Dialogue is shown in the text box below these two windows; members of each team can communicate regardless of distance, but in-team dialogue is displayed only to members of that team. Participants can choose to interact either within their team or with all participants in the MUVE at that time. To aid their interactions, participants also have access to one-click interface features that enable the avatar to express (through stylized postures and gestures) emotions such as happiness, sadness, and anger. These interface features also allow looking upward or downward and seeing the world from a first-person perspective or from behind one's own body in a third-person viewpoint.

Multiple teams of students can access the MUVE simultaneously, each individual manipulating an avatar through their computer. In our implementations, the class is divided into teams of two to four students, which are "sent back in time" to this virtual environment. The lab notebook the student teams use asks the class to help the city solve its environmental and health problems, which are directly related to middle school science content. To accomplish this, the students must collaborate to share the data each team collects. Beyond textual conversation, students can project to each other "snapshots" of their current individual point of view (when someone has discovered an item of general interest) and also can "teleport" to join anyone on their team for joint investigation. In-group collaboration is visible only to other group members. Each time a team reenters the world, several months of time have passed in River City, so that learners can track the dynamic evolution of local problems.

Learners are engaged in a "participatory historical situation" in which they can apply tools and knowledge from both the past and the present to resolve an authentic problem. In this "back to the future" situation, students' mastery of 21<sup>st</sup> century classroom content and skills empowers them in the 19<sup>th</sup> century virtual world. Figure 3 shows the 19<sup>th</sup> century laboratory equipment representative of what students can use to aid themselves in River City. An eventual goal of our work, not currently implemented, is the capability of interaction with some digital artifacts. For example, were a learner to double-click on a piece of apparatus, such as a microscope, the corresponding avatar would look through a virtual microscope; and the image from the microscope slide would appear in the right-hand interface-window.

Figure 4 presents water quality data from one of eleven water-sampling stations in River City. Potentially, at the high school level, this could link to virtual laboratory equipment applications such as the irYdium project at Carnegie Mellon University (<http://ir.chem.cmu.edu/irproject/>), so that students could conduct their own analyses rather than receiving the experimental results. Through data gathering, students observe the patterns that emerge and wrestle with questions such as "Why are many more poor people getting sick than rich people?" Multiple causal factors are involved, including polluted water runoff to low-lying areas, insect vectors in swampy areas, overcrowding, and the cost of access to medical care. Eventually, we hope to develop the

capability for participants' avatars to become ill if they behave in ways that trigger these factors in the environment, thus increasing students' sense of immersion in the world.

Throughout the world, students encounter residents of River City and "overhear" their conversations with one another. These nonplaying characters (NPCs) are computer-based "agents" who disclose information and indirect clues about what is going on in River City [Figure 5]. As with the content displayed in the right frame, the phrases "spoken" by NPCs vary according to a student's level.

The main goal of the MUVE is to teach students the skills necessary for scientific inquiry, such as would be important in conducting investigations for a science fair project. This goal follows the National Science Education Standard A for scientific inquiry in 5-8 grades (<http://www.nap.edu/readingroom/books/nse/html/6d.html>). The emphasis in the MUVE is on identifying a problem, and therefore, River City has multiple lines of potential exploration. As mentioned above, there are 3 main strands of illness in River City. Some inhabitants have intestinal upsets from water contaminated by sewage. The sewage reaches the river from deliberate outflow of the flush toilets newly introduced to the wealthy homes in the mountains. This contaminated water flows downstream to the swampy lands behind the tenement homes used by the poor as potable water. This potential strand of investigation aligns with Standard F, Science in Personal and Social Perspectives, and demonstrates to students the complications of human activity as well as the effect of differing living conditions on disease transmission (e.g., the wealthy live in single family homes upstream, while the poor live downstream in crowded conditions promoting disease contagion). In addition, some of the city wells, used by middle class residents and hotel guests, are also contaminated from street runoff of manure. Investigating the water contamination integrates the students' knowledge of the water cycle, Standard D, Earth Science, with the historical aspects of River City.

The second disease strand is the introduction from outside of tuberculosis and the patterns that emerge of its spread throughout River City. The students' awareness of the passage of time is particularly interesting for this disease and for the last, malaria. Malaria, endemic to many areas of the U.S. in the 1800's, follows the life cycle of its carrier, the mosquito. As a result, as the students log in each day, they are able, if this problem is of interest to them, to follow the rise and fall of new cases of malaria from summer to winter and back again. These three diseases were chosen to represent three different disease vectors: water-borne, air-borne, and insect-carried, and align with Standard C, Life Science.

These three disease strands are integrated with historical, social and geographical content to allow students to experience the realities of identifying a problem, from within a content-rich environment, to investigate. Many students learn in schools the unrealistic view that there is a single right answer in science, easily discernible. In exploring River City, however, students are each guided in teams to make a unique hypothesis regarding one of many problems, based on their own interest. At the end of the project, they compare their research with other teams of students to discover the plethora of potential hypotheses and avenues of investigation available for exploration.

During their time in the MUVE, students answer questions in a Lab Notebook, which the teachers later use for assessment purposes. The Lab Notebook starts with questions that guide exploration of the environment and develop mastery of the interface, building towards later investigations that are content specific and require completing a data table based on the water

samples encountered in River City. At the end, students write a letter to the mayor of River City describing the health and environmental problems they have encountered and making suggestions for improving the life of the inhabitants.

Over time, we plan to add various capabilities that may enhance participants' motivation and engagement. In addition to features listed earlier, these include:

- An avatar can gain new powers through mastering skills and knowledge. Learners who master science content and investigative skills can attain higher "levels of performance" in which they can use doors and objects that lower level participants cannot. To keep the interactions collaborative and to help all participants learn, part of attaining a level is based on helping a less adept student master content and skills through peer mentoring, thus keeping all students on close to the same levels.
- As students succeed in resolving problems in River City, new images can appear in the world (clearly labeled as pseudo-historical objects) in which the learners are shown as co-habiting the historical environment with figures from the past. These non-player-character (NPC) avatars can provide specific information about the environment and their lives, information necessary for identifying and solving problems related to the curriculum on which the unit is based.
- Historical figures can appear as avatars to guide students in resolving the problems in River City (parallel to encountering an actor playing Thomas Jefferson on a visit to historic Williamsburg). For example, Ellen Swallow Richards (the first woman to graduate from MIT) was a pioneer in water quality treatment and is the "patron saint" of River City. Contemporary experts such as public health officials could also at times assume avatar roles in the MUVE to illustrate present day water quality issues in the U.S. and in developing countries. Such figures could provide not only mentoring, but also role models, especially for young women and minority students fighting cultural stereotypes about learning science.
- Students can travel through time to the same location at different historical eras to develop an understanding of how use of natural resources and technologies affect both the quality of life and the environment. For example, while situated in River City during the 1960s, students could gather information from a Rachel Carson-like historical figure to assess the effect of pesticides on water quality, the environment, and crop yields. They could also have access to antibiotics for treating illnesses caused by water-borne diseases.

Videogames and chat tools that incorporate some of these features seem quite motivating to many children.

## **PILOT IMPLEMENTATIONS IN PUBLIC SCHOOL CLASSROOMS**

In our pilot implementations of River City, using three public school classrooms in Boston, MA and one in Arlington, VA, we have examined usability, student motivation, and classroom implementation issues. This study reports from outcomes at our initial pilot site, Gunston Middle School in Arlington, Virginia; at the time of submission, results from the Boston implementation were not yet available. The Gunston Middle School student population has about 55% free and reduced lunch pupils and 70% English-as-a-Second-Language learners. We selected Gunston as our first pilot site for several reasons: The school has a very diverse population, both socio-economically and ethnically; it is conveniently located to both the Smithsonian and to George Mason University where most of the research and development teams are housed; and the site

already has a good technology infrastructure to support the connectivity and bandwidth requirements of the project. Also, Gunston is a language immersion school, so representative populations of students who take science in either English or Spanish were available. From the very beginning of the project, we included both Gunston seventh grade science teachers on our development team to ensure that learning experiences within the MUVE both met the needs of diverse students and were practical to implement given typical classroom and curriculum constraints. The teachers were happy to join us in the development process because they are seeking ways to motivate and aid underperforming students and also want to enhance bilingual learning through science materials.

During February 2002, eighteen seventh-grade students at Gunston Middle School in Arlington, Virginia, participated in the River City Unit. Due to scheduling constraints and a computer lab availability problem exacerbated by construction renovation at the school, we scheduled three groups of six students to two “in-school” field trips of half a day each. Students were offered regular breaks to coincide with the normal 43-minute periods, though many preferred to work straight through. Below are our findings about usability, motivation, and implementation from this and prior studies; we are now analyzing data on learning. We also are conducting implementations in two Boston Public School classrooms.

### **FINDINGS ABOUT USABILITY, MOTIVATION, AND IMPLEMENTATION**

In terms of usability, all students mastered the interface readily upon their first exposure. Apart from a general familiarity with the concept of navigating through different levels of content to get information, which they get from using Web browsers, middle school students regularly use Instant Messaging and other chat-type applications. Almost all have experience playing computer and video games that involve navigating through a three-dimensional space. No problems particular to our MUVE interface were noted.

In terms of motivation, students were highly engaged by the environment, its content, and the opportunity to collaborate. Some of this motivation undoubtedly stems from the novelty of using a game-like computer environment during class time and from the adoption of an avatar character. However, strong engagement persisted through detailed work in the Lab Notebook after this novelty effect had worn off. Collaboration among students was quite pronounced; the teachers felt some students did better group work in the MUVE than in face-to-face settings.

Implementation of the MUVE did not pose issues for our teachers at the Gunston site, beyond access to a computer lab. For a variety of reasons, this was problematic for teachers during the time the MUVE was used at their school, necessitating a variety of work-arounds. Teachers reported that the high level of student engagement aided with classroom management, and occasional crashes of individual students’ MUVE application were rapidly remedied.

### **CONCLUSION**

To date, no one has studied whether MUVES are a type of educational application suited to use in schools, linked to core curriculum. Our research to date demonstrates that MUVES seem quite feasible as an addition to more conventional kinds of computer-based instruction. High levels of student motivation, coupled with good usability and a lack of implementation problems, is a promising beginning for this emerging interactive medium. Our studies of students’ educational outcomes in the MUVES we developed will further clarify the strengths and limits of this approach to learning.
